- Introduction

This project focuses on improving student productivity by tracking study sessions. Many students struggle with procrastination and inaccurate estimation of study time. This system provides a simple way to monitor actual study duration and improve time management.

- Task 1 – Problem Identification

The problem was identified through common student behavior where study time is often mismanaged. Students tend to overestimate productivity and lack consistency. This project addresses the need for a simple tracking system.

- Task 2 – Approach

The approach involves creating a session-based tracker where users can start and stop study sessions. The system records time and categorizes it based on subjects, allowing users to analyze their study habits.

- Task 3 – Implementation

The project is implemented in Python using time functions and JSON storage. It maintains active sessions and calculates total study time per subject. The design is modular and easy to use.

- Task 4 – Challenges

Handling real-time tracking and ensuring sessions are properly closed was challenging. Managing edge cases like stopping without starting required additional checks.

- Task 5 – Learning

This project helped in understanding time-based functions, data persistence, and building user-focused solutions. It also improved logical thinking.

- Conclusion

The project successfully provides a simple solution to track study habits. It demonstrates practical application of programming concepts to solve real-life problems.
